INTRODUCTION

Waste activities series nickel mining activity in Indonesia. Mining involves sediment through particle binding material respectively. Jl. Pasir City, would accumulate in waters can be used as a biological indicator of water pollution of rivers as well as lake. Suso snail (Tylomelania patriarchalis) is one of macrozoobentos organism which is abundance in Matano Lake and consumed by the peoples surrounding of the lake. Therefore, data of heavy metals concentration at the bottom layer of the waters having mining activities is required to determine a status of water pollution, but there is a limit information in Matano Lake.

NICKEL (Ni) endangers to human health. Direct contact of Ni salts solution to human skin could affect dermatitis, whilst breathing Ni affects on lung cancer (Effendie, 2000). According to Sudarmaji et al. (2006), chromium (Cr) could worst affect on respiratory tract, skin, blood vessel, and knee.

Nickel of 237 and 301 mg/L gives death effect on larvae and embryo of mussels, respectively. Eisler (1998) reported that total death of fresh water snail and mollusc embryos were at a level of 237 dan 301 mg/L, respectively. Value of LC50 for fresh water snail Juga plicifera was 237 mg Ni/L for 96 exposure hours, whilst mollusc adult of Mya arenaria has LC50 at 112 mg Ni/L for 168 exposure hours. Chromium also affect on lethal death for some aquatics animal. Vutukuru (2005) stated that LC50 for Labeo rohita was 39.4 mg Cr/L for 96 exposure hours.

It had been approved that Ni and Cr in waters would be deposited in bottom layer of the waters. Therefore, a research was done for observing Ni and Cr concentration on sediment and suso snail at the bottom layer of Lake Matano, South Sulawesi.

MATERIALS AND METHODS

The research was conducted on July-August 2004 in Matano Lake, South Sulawesi. Some stations were established proposively in 4 places with a distance of 50 m from offshore of the lake. Determination of the
station was based on distance of a source of mining activity, namely station A (25 km), station B (14 km), station C (5 km), and station D (7 km) respectively. Each station was divided by three substation having 75-100 m in distance (Figure 1).

In each station, samples of sediment and suso snail were collected using Eickman Grab at 1-5 m water depth according to availability of snail. The mud and snail was separated using hand, kept in labeled plastic bag and then hold in cool box at a temperature level of 4°C. Only 12 snails were taken from each station as a subject to laboratory analysis.

Sediment was dried using room temperature for 48 hours in the laboratory. There after, dried sediment was sieved using sieve net of 0.125 mm in diameter and taken out in amount of 2 g as a subject to heavy metal analysis. The diluted samples was dried and ready to be analyzed using Atomic Adsorption Spectrofotometry Perkin Elmer Analyst 7,000. Each sample was analyzed with 3 replicates (APHA, 1980).

Data was analyzed statistically using Kruskall-Wallis and Mann-Whitney test for evaluating differences of nickel and chromium concentration in sediment and suso snail. Model of regression is:

\[ Y = a + bX \]  \hspace{1cm} (1)

where:

- \( Y \) = concentration of nickel or chromium in suso snail (mg/kg)
- \( X \) = concentration of nickel or chromium in sediment (mg/kg)
- \( a \) = intercept
- \( b \) = slope

**RESULTS AND DISCUSSION**

The data showed that the concentration of nickel in each sampling station was relatively high (Figure 2). The highest concentration was 5,277.5 mg/kg found in station C relatively close to the nickel processing plant (±5 km). The lowest nickel concentration was found in station A which was 2,009.83 mg/kg. Station A was the furthest located 25 km away from nickel processing plant. The highest nickel concentration in station C might be caused by its location near from mine activities such as open mining soil and processing plant. It caused run-off sediment entering to the Matano Lake water column marked by yellow brown sediment colors likely found in station C.

Land clearing in mine activity at Matano Lake surrounding caused run-off entering to the Matano Lake waters during rainy season. Connel & Miller (1984)
stated that open mining activities leaving the soil surface exposed could cause soil and rock decaying process rapidly and carrying some minerals and metals in water column.

Haffner (2000) in his latest investigation stated that nickel concentration in sediment at Lake Matano varied from 12,000-30,000 mg/kg. Moore (1991) in Effendie (2000) stated that nickel concentration naturally found in soil about 75 mg/kg. Moreover, Cataldo & Wildug (1978) stated that nickel concentration naturally found in soil varied from 10-1,000 lg/g.

Nickel concentration in sediment was high at sampling station D, located about 7 km from nickel processing plant and mining area. Average of nickel concentration in sediment found in station D was high, up to 3,681.25 mg/kg. As close to the nickel processing plant, the station received more waste. That was proved by waste concentration in inlet locating in station D (Figure 1). The Kruskall-Wallis test showed that nickel concentration in sediment at each sampling station was significantly different (p<0.01). It meant that sampling station C and D were the most receiving nickel waste from processing plant and mining area whilst sampling station A and B were less.

Nickel concentration in suso meat at each sampling station was relatively high (Figure 3). The highest average nickel concentration was observed at station B (293.84 mg/kg) and the lowest was at station C (50.813 mg/kg). The Kruskall-Wallis test inter-sampling station showed that average nickel concentration of suso snail in each sampling station was significantly different (p<0.01). The symptom of nickel concentration in suso snail was high, up to 3,681.25 mg/kg. As close to the nickel processing plant, the station received more waste. That was proved by waste concentration in inlet locating in station D (Figure 1). The Kruskall-Wallis test showed that nickel concentration in suso at each sampling station was significantly different (p<0.01). It meant that sampling station C and D were the most receiving nickel waste from processing plant and mining area whilst sampling station A and B were less.
average of chromium concentration in suso snail was significantly different (p<0.05).

Station C is one of sampling station close to the nickel processing plant. The highest chromium concentration in suso snail meat at Station C was probably influenced by chromium concentration in sediment. Chromium concentration in sediment was nearly similar at each sampling station, except in suso snail. Kruskall-Wallis test showed that chromium concentration in suso snail was very significantly different (p<0.01) in each sampling station. This also may indicate that suso snail has a different ability in absorbing metal.

Regression analyze showed that chromium concentration in suso snail was linear and positive following the equation \( Y = 0.0883X - 0.1981 \), where \( Y \) = chromium concentration in suso snail, and \( X \) = chromium concentration in sediment. \( R^2 \) is 0.5807 whilst coefficient correlation (r) is 0.7620 (Figure 7).

High concentration of chromium at each sampling station indicated that suso snail was not properly consumed. WHO (2000) determined that chromium concentration in food is not exceed the threshold limit 0.05 mg/kg.

CONCLUSION

1. The highest Ni concentration in sediment was observed in station C (5.277.5 mg/kg) and significantly different (p<0.01) to other sampling stations. Concentration of Cr was not significant in each station. The highest concentration of the metals in the snail was observed in station C (0.58 mg/kg) for Cr and in station B (293.84 mg/kg) for Ni.

2. Concentration value of nickel and chromium in suso snail (Tylomelania patriarchalis) in Matano Lake was lower than in sediment. There is positive correlation between nickel and chromium concentration in sediment and suso snail (Tylomelania patriarchalis).

ACKNOWLEDGEMENT

This research was budgeted by individual funding. I would like to thank to the head and staffs of Laboratorium Dinas Perindustrian dan Perdagangan Provinsi Sulawesi Selatan who help us to analyze material samples.
